1 EDA and Data Cleaning

Assignment: Exploratory Data Analysis (EDA) and Data Cleaning Report

1.1 Dataset Overview:

1.1.1 Yahoo Finance API

The data that will be used for my capstone can be accessed through the Yahoo Finance API.

The Yahoo Finance API is a free popular API that is used by developers to load in a variety of stock data. This includes financial, candlestick and other information that can be utilized to make informed investment decisions.

Yahoo Finance is free and very easy to set up. First pip install yfinance and then simply load it into your notebook.

```
[ ]: # load the API in
import yfinance as yf # yf is the usual name for the package
```

The YFinance API offers stock candlestick data, information about the stock as well as financial/balance sheets. This can be utilised to create a number of analysis such as fundamental and technical analysis. This project will have a concentration in technical analysis which looks at the price of the stock.

Candlestick Data Candlestick data is used for a variety of techniques in investing as it holds the crucial information associated with the price of the stock throughout the trading day. This can be used to create a deeper understanding of how the stock changes on a day to day basis.

The columns contain candlestick data which is:

- 'Open' : The price of the equity at the beginning of the trading day.
- 'High' : The highest price of the equity throughout the day.
- 'Low' : The lowest price of the equity throughout the day.
- 'Close' : The price of the equity at the end of the trading day
- 'Adjusted Close' : The came as closing price however it takes dividends, stock splits and new stock offerings into account
- 'Volume': The number of times that equity is traded within a day.

```
[ ]: # save the ticker information of 'MSFT' as a variable
msft = yf.Ticker('MSFT')

# download the candlestick data
msft_candlestick = yf.download('MSFT', start='2020-01-01', end='2024-01-01')

# display the dataframe
msft_candlestick
```

1.1.2 Stock Data

There are thousands of equities to choose from on the stock market, to reduce the overload of data that will be used in training the trading techniques sector ETF's will be used instead.

Exchange Traded Funds (ETF) Electronically Traded Funds or ETF's are an investment equity which has a basket of securities that tracks or seeks to outperform indexes. It takes a smaller proportion of a large number of individual stocks so that the equity is a broader representation of a specific idea. For example if you want to invest in small-cap companies, there are a number of ETF's that can be used to take a smaller investment of a hundred companies rather than one. This looks to spread out investments to reduce risk.

Economic Time Periods The macroeconomic business cycle is the representation of overall economic activity within the economy. During different periods of economic activity the market sectors will react differently. The following are the typical components of the macroeconomic business cycle.

- Trough : This is the low point of the economy where supply is in excess and demand is in shortage. This can turn into a recession which is where there are two consecutive quarters where the GDP growth is negative.
- Expansion : Following a trough, there is a period of economic growth which leads to an increase in consumer and business confidence. This will result in an increase in wage growth and a decrease in unemployment. Expansion periods should be steady and not exponential to ensure prolonged prosperity.
- Peak : A peak occurs when an expansion has reached its limit and there ends up being downward pressure on the growth rate within economic activity. Businesses will then reevaluate their decision making to review budgets and other outlooks.
- Contraction : This is when growth slows, unemployment increases and business investment falls.

```
[ ]: # create time periods for where this takes place
economic_cycle_periods = {

    "trough": ("2008-10-01", "2009-06-01"),
    "expansion": ("2012-01-01", "2015-01-01"),
    "peak": ("2019-06-01", "2020-02-01"),
    "contraction": ("2007-12-01", "2008-10-01"),
}

economic_cycle_periods_list = ['trough', 'expansion', 'peak', 'contraction']
```

GICS Sectors According to Global Industry Classification Standard there are 11 major sectors at play within the economy. Each with their own industries and sub-industries but this capstone project there will be a concentration on the sectors.

For the capstone project a concentration on ETF's that represent the sectors will be used to help understand how different sectors will perform. The following ETF equities are going to be invested in based on their sector. More information about the equities can be found in the report.

- Materials : XLB
- Industrials : XLI
- Financials : XLF
- Information Technology : XLK
- Consumer Discretionary : XLY
- Consumer Staples : XLP
- Energy : XLE
- Healthcare : XLV
- Communication Services : VOX
- Utilities : XLU
- Real Estate : IYR

```
[ ]: # create etf tickers for sectors
sector_etf_tickers = [
    'XLB', # materials sector
    'XLI', # industrials sector
    'XLF', # financials
    'XLK', # information technology
    'XLY', # consumer discretionary
    'XLP', # consumer staples
    'XLE', # energy
    'XLV', # healthcare
    'VOX', # communication services
    'XLU', # utilities
    'IYR' # real estate
]
```

1.1.3 Nested Dictionary Storage of Relevant Data

Using the YFinance API load in candlestick data with the 11 industry sectors during the four different economic time periods. This can be used to evaluate sector etfs during different economic time periods using the daily adjusted closed price.

```
[ ]: # save nested dictionary data as a variable to be accessed.
sector_etf_data = {}
↳download_stock_data_for_periods(sector_etf_tickers,economic_cycle_periods)

Missing Data Values ‘download_stock_data_for_periods’ function checks to make sure if there are any missing dates for any of the stocks it will return a dataframe with those that are missing. However each sector etf seems to have all data so there is no missing data.

Accessing specific data The following is an example of how you can access the healthcare ‘XLV’ sector ETF during the trough time period.

```
[ ]: # access healthcare sector during an expansion
# first load in the trough data
trough_sector_data = sector_etf_data['trough']
```

```
[ ]: # now access the healthcare sector etf 'XLV'
trough_sector_data['XLV'].head()
```

```
[ ]:          Open      High      Low      Close  Adj Close  Volume

```

This returns the candlestick data for the XLV equity during a trough which ranged from 2008-01-02 to 2009-6-30 due to the Global Financial Crises.

The same process can be completed in one step.

```
[ ]: # access 'XLV' equity in one line of code
sector_etf_data['trough']['XLV'].head()
```

```

```

This is extremely useful for technical analysis which is heavily reliant on historical data. There is now an easy process to access any stock data's candlestick data (in this case sector ETF's) during any time period (different macroeconomic time periods). This is going to be used to as a basis for the capstone project.

There are currently 6 columns however this will grow as different techniques require new columns to be used as features.

The size of the data currently stands at: 4 time periods which as - 166 (trough) - 754 (expansion) - 169 (peak) - 209

This is equal to 1298 trading days. Each trading day has 11 sector ETF's each with 6 columns which is 114,224 data points.

1.2 Initial Data Inspection / Univariate Analysis

The dataset is a nested dictionary with a number of time series. Using typical descriptive statistics might not be as relevant. Using the create_analysis function you are able to load in the nested dictionary and apply different descriptive statistical reports on the different sector etfs during different time periods as a table. This can be adjusted to fit a number of descriptive statistics and for different parameters within the dataframe of the nested dictionary.

1.2.1 Numerical Analysis

Initial Numerical Analysis Looking at the descriptive statistics of the different sector etfs during different time period can help observe how the data changes from the beginning to the end of the period. This will be helpful for initial understanding of how investments change during different macroeconomic cycles.

```
[ ]: # get the mean value of these stocks during the different time periods
mean_data = create_analysis(sector_etf_tickers,economic_cycle_periods_list,sector_etf_data,'AdjClose','mean')
mean_data
```

```
[ ]:

1.2.2 Visualisation

Creating a dashboard that can be used to adjust different time periods/stocks to visualise your stock data through candlestick data would be extremely useful. This will be done later. For now use the ‘visualize_candlestick’ function to plot candlestick data.

```
[ ]: # create a sample visualisation of 'XLV' healthcare ETF from 2009-06 to 2010-01-01
for period in economic_cycle_periods_list:
    visualize_candlestick(sector_etf_data[period]['XLV'],f'XLK {period}')
```

Observe the movement of the XLK healthcare sector etf and how it changes during different macroeconomic time periods. Good for initial inspection to averaging all of the stocks during the different macroeconomic cycles will be a better representation of the movement of the market.

1.3 Stock Investment: Buy and Hold

An extremely popular type of investment is a passive one, this is where individuals will see an opportunity for long term growth of an equity and will simply purchase the stock and hold onto it

for a varied period of time. As the beginning component of analysis, use a buy and hold strategy to look at the different stocks during different time periods to determine yearly return on investment

1.3.1 Return on Investment Simple Model

The simple model is going to purchase the sector etf at the start of the time period, then hold onto it. This is extremely reliant on the time the stock is purchased and is simply down to luck. However, it is going to show a rough understanding of how the price of the stock changes. The timing has a bit of wiggle room so that it goes from the previous cycle to the current cycle to represent how it changes.

```

1.3.2 Stochastic Numerical Analysis

The downside of the initial numerical analysis is that it only takes in one event of where you buy at the start of the period and sell at the end of the period. This is going to make time period and time of investment be a parameter which impacts the expected return. To overcome this stochastic modeling can be performed.

By performing a stochastic model where different time periods of initial investment and holding onto the equity for a set period takes away the included parameters. This isolates the expected return more. It can also be repeated over a number of samples which can then increase the likeliness of it being a true representation of the data. A histogram can also be created to observe how different returns on investment are observed. This probabilistic value can be used to display the probability distribution function and a cumulative distribution function can be created.

Calculating Expected Returns The ‘stochastic_modeling’ function is going to go through each equity during each time period and take n samples of initial start dates and purchase one sector ETF. This is held for a month and then sold off. By repeating the model 1000 times you get a distribution of returns which can be used to understand expected returns and standard deviations which is essential for understanding which sector is best for different time periods and to understand how the data is distributed.

```
[ ]: # create an adjusted close price sector etf dictionary which can changed based
      ↪on the macroeconomic period
adjusted_close_sector_etf =
      ↪get_adjusted_closed_price(sector_etf_data,sector_etf_tickers,economic_cycle_periods_list)

[ ]: # take 1000 samples of different initial purchase dates, hold the equity for 30
      ↪days then compare it with the start
expected_values_sector_etf_buy_hold =
      ↪stochastic_modeling(adjusted_close_sector_etf,sector_etf_tickers,economic_cycle_periods_list)
expected_values_sector_etf_buy_hold['trough']['XLK'][0:5]

[ ]: [-2.233114541074024,
      -7.916431375114681,
      6.40207475775085,
      9.35615165782157,
      -20.50455454243595]
```

Visualising Expected Returns A dashboard is going to be used to create a visualisation of any sector etf during any time period however the following will display one sector etf during the different economic time periods.

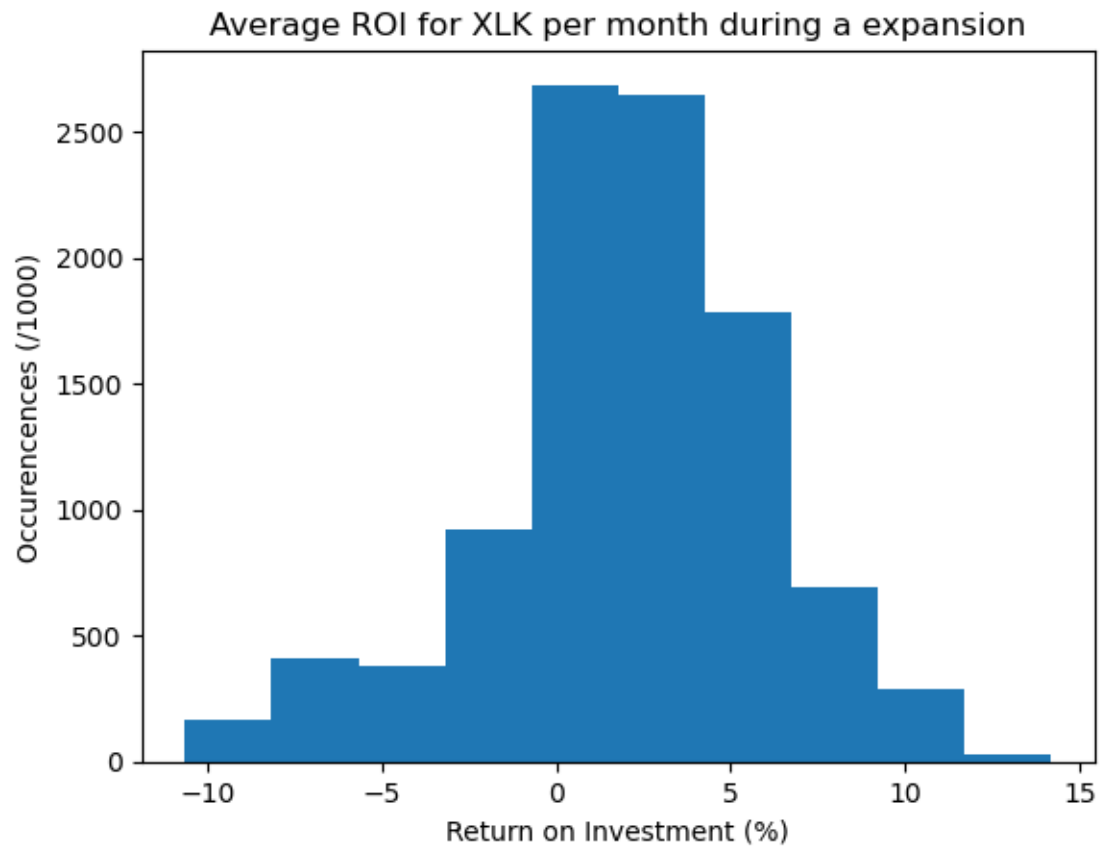

```
[ ]: # example case of expected values by sampling

import matplotlib.pyplot as plt

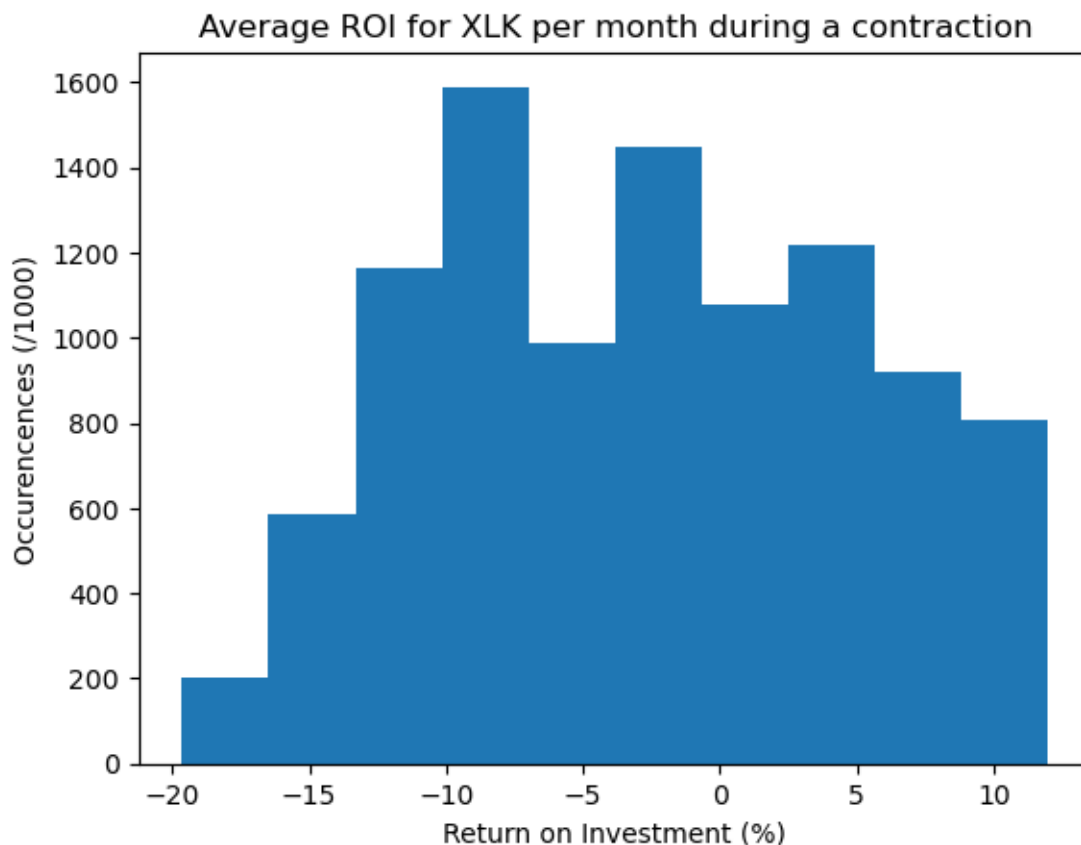

for period in economic_cycle_periods_list:
    plt.hist(pd.
      ↪Series((expected_values_sector_etf_buy_hold[period]['XLK'])))
    plt.ylabel('Occurences (/1000)')
    plt.xlabel('Return on Investment (%)')
    plt.title(f'Average ROI for XLK per month during a {period}')
    plt.show()

    """
    print('Standard Deviation:')
    print(pd.Series(expected_values_sector_etf_buy_hold['expansion']['XLK']).std())
    print('Median:')
    print(pd.Series(expected_values_sector_etf_buy_hold['expansion']['XLK']).
      ↪median())
    print('Mean:')
    print(pd.Series(expected_values_sector_etf_buy_hold['expansion']['XLK']).
      ↪mean()) """
```

```
[ ]: "\nprint('Standard Deviation:')\nprint(pd.Series(expected_values_sector_etf_buy_
hold['expansion']['XLK']).std())\nprint('Median:')\nprint(pd.Series(expected_val
ues_sector_etf_buy_hold['expansion']['XLK']).median())\nprint('Mean:')\nprint(pd
.Series(expected_values_sector_etf_buy_hold['expansion']['XLK']).mean())"
```

The standard deviation is only useful if the data has a normal distribution. None of the data looks to be exactly normal but it looks close to normal.

Summarising Expected Results Create a table for - Mean - Median - Standard Deviation - Variation
